New Support for a Late-Pleistocene Coastal Occupation at the Indian Sands Site, Oregon

Loren G. Davis

Archaeological investigations at the Indian Sands site (35CU67c) on Oregon’s southern coast produced evidence of repeated cultural occupation beginning in the late Pleistocene into the Holocene (Davis et al. 2004; Moss and Erlandson 1998). Previous papers have dealt with the site’s geoarchaeological context (Davis 2006; Davis et al. 2004), lithic technology (Willis 2004, 2005), and marine
faunal remains (Moss and Erlandson 1998). This paper presents new thermoluminescence (TL) assays that support claims for a late-Pleistocene occupation.

Archaeologically relevant stratigraphic units at 35CU67c include pedogenically altered aeolian sediments of the 3Ab horizon, which are unconformably overlain by aeolian sands of the 2C horizon (Figure 1). Davis et al. (2004) argue that the lower part of 3Ab contains a late-Pleistocene cultural occupation based on a 10,430 ± 150 RCYBP (12,300 ± 490 CALYBP) date from wood charcoal excavated in situ in the lower part of the 3Ab horizon in direct stratigraphic association with lithic artifacts, positioned ca. 10 cm above the 3Ab-4Bsb contact. The position of this AMS date is plausible given its stratigraphic position relative to other chronometric dates at the site (Figure 1).

In 2003, a vertical series of four TL samples were collected from the 3Ab horizon in excavation Unit F to test the site chronostratigraphy established by Davis et al. (2004). TL samples were collected in copper tubes 10 cm long and 3 cm in diameter, driven into a freshly cleaned profile in Unit F. Background radiation samples were taken 2 cm above and below each of the TL sample tubes. These samples were sent to Nicholas Debenham at Quaternary TL Surveys in Nottingham, UK, and were studied following a standardized set of pretreatment and analytical methods (available at http://www.users.globalnet.co.uk/~qtls/index.htm#contents). These four TL samples returned ages between 9030 ± 900 CALYBP and 6440 ± 670 CALYBP (Figure 1).

Luminescence dating of pedogenic horizons can be problematic owing to mixing of sediments with widely variable exposure histories; however, in a

![Figure 1](https://www.users.globalnet.co.uk/~qtls/index.htm#contents)
depositional context where sediments accumulate slowly and are subjected to limited vertical mixing, the use of luminescence dating may reveal when a stratigraphic unit was completely buried and no longer subject to the processes of bioturbation. As sediments gradually accumulate, this zone of bioturbation is incrementally elevated and deeper portions of the deposit no longer receive light-exposed sediments. Once sediments achieve this level of stability they begin to accumulate a TL signal. In this context, a TL date from the 3Ab horizon indicates when that portion of the site was fully buried and no longer influenced by bioturbation. Thus these new TL ages provide minimum limiting ages on deposition since the timing of sedimentation must be older than their associated TL age. The 3Ab TL chronology supports the previous interpretation made by Davis et al. (2004) that early hunter-gatherers occupied Indian Sands during the terminal Pleistocene and provides a means of separating early from later cultural components.
